Modelling of spectra

Cubic symmetry of Hamiltonian predicts *triply degenerate* optic mode at Γ in both cases.

2+1 optic mode structure of BN violates group theoretical prediction.

Phenomenon known as **LO/TO splitting**.

Modelling of spectra

- Dipole created by displacement of charges of long-wavelength LO mode creates induced electric field.
- For TO motion $\mathbf{E} \perp \mathbf{q} \Rightarrow \mathbf{E} \cdot \mathbf{q} = 0$
- For LO mode $\mathbf{E} \cdot \mathbf{q} \neq 0$ and E-field adds additional restoring force.
- Frequency of LO mode is upshifted.
- Lyndane-Sachs-Teller relation for cubic case: $\frac{\omega_{LO}^2}{\omega_{TO}^2} = \frac{\epsilon_0}{\epsilon_\infty}$
- LO frequencies at $\mathbf{q} = 0$ depend on *dielectric permittivity*

Dynamical charges in
NaHF2

Modelling of spectra

LO-TO splitting at $\mathbf{q} \rightarrow 0$ is automatically included in DFPT. At $\mathbf{q} = 0$ exactly, need to add additional *non-analytic* term to dynamical matrix

$$C_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q} = 0)(NA) = \frac{4\pi}{\Omega_0} \frac{\sum_{\gamma} q_{\gamma} Z_{\kappa,\gamma\alpha}^* \sum_{\gamma'} q_{\gamma'} Z_{\kappa',\gamma'\alpha'}^*}{\sum_{\gamma\gamma'} q_{\gamma} \epsilon_{\gamma\gamma'}^{\infty} q_{\gamma'}}$$

$\epsilon_{\gamma\gamma'}^{\infty}$ is the dielectric permittivity tensor

$Z_{\kappa,\beta\alpha}^*$ is the Born Effective Charge tensor

$$Z_{\kappa,\beta, \text{alpha}}^* = V \frac{\partial P_{\beta}}{\partial x_{\kappa,\alpha}} = \frac{\partial F_{\kappa,\alpha}}{\partial E_{\beta}}$$

Z^* is *polarization per unit cell* caused by displacement of atom κ in direction α or *force exerted on ion* by macroscopic electric field.

$Z_{\kappa,\beta\alpha}^*$ and $\epsilon_{\gamma\gamma'}^{\infty}$ can both be computed via DFPT response to *electric field* perturbation.

(Dipole-dipole model use for Coulombic tail correction in Fourier interpolation procedure also depends on Z^* and ϵ^{∞} . *Not* included in most supercell calculations \Rightarrow be suspicious of convergence in case of polar systems).

Modelling of spectra

- Can also apply DFPT to *electric field* perturbation.
- Need trick to evaluate position operator. Evaluate $\nabla_{\mathbf{k}}\phi$. See NMR lecture for details.
- set **task = efield** or **task = phonon+efield**
- Convergence controlled by **efield_energy_tol**
- Computes *dielectric permittivity* for crystals and *polarisability* (for molecules)
- Includes *lattice contribution* for $\omega \rightarrow 0$ response.
- Writes additional file *seedname.efield* containing $\epsilon_{\gamma\gamma'}(\omega)$ in infrared region.

Modelling of spectra

- Unusual bonding, nominally ionic $\text{Na}^+ \text{FHF}^-$, with linear anion.
- Layer structure, $R\bar{3}$ space group.
- Phase transition to monoclinic form at ≈ 0.4 GPa.
- Phonon spectrum measured at ISIS on TOSCA
 - ◆ high-resolution neutron powder spectrometer.
 - ◆ No selection rule absences
 - ◆ Little or no anharmonic overtone contamination of spectra
 - ◆ No control over (\mathbf{q}, ω) path - excellent for molecular systems but spectra hard to interpret if dispersion present.

To model spectra need to treat scattering dynamics of incident and emergent radiation.

In case of INS interaction is between point neutron and nucleus - scalar quantity b depends only on nucleus – specific properties.

$$\frac{d^2\sigma}{dEd\Omega} = \frac{k_f}{k_i} b^2 S(\mathbf{Q}, \omega)$$

\mathbf{Q} is scattering vector and ω is frequency - interact with phonons at same wavevector and frequency.

Full measured spectrum includes overtones and combinations and instrumental geometry and BZ sampling factors.

Need specific spectral modelling software to incorporate effects as postprocessing step following CASTEP phonon DOS calculation.

Prediction of reflectivity of optically flat single crystal surface given as function of q - projected permittivity $\epsilon_q(\omega)$

$$R(\omega) = \left| \frac{\epsilon_q^{1/2}(\omega) - 1}{\epsilon_q^{1/2}(\omega) + 1} \right|^2$$

with ϵ_q defined in terms of ϵ^∞ and mode oscillator strength $S_{m,\alpha\beta}$

$$\epsilon_q(\omega) = \mathbf{q} \cdot \epsilon^\infty \cdot \mathbf{q} + \frac{4\pi}{\Omega_0} \sum_m \frac{\mathbf{q} \cdot \mathbf{S} \cdot \mathbf{q}}{\omega_m^2 - \omega^2} = \mathbf{q} \cdot \epsilon(\omega) \cdot \mathbf{q}$$

$\epsilon(\omega)$ is tabulated in the *seend-name.efield* file written from a CASTEP efield response calculation.

Raman scattering depends on raman activity tensor

$$I_{\alpha\beta}^{\text{raman}} = \frac{d^3 E}{d\varepsilon_\alpha d\varepsilon_\beta dQ_m} = \frac{d\varepsilon_{\alpha\beta}}{dQ_m}$$

i.e. the activity of a mode is the derivative of the dielectric permittivity with respect to the displacement along the mode eigenvector.

CASTEP evaluates the raman tensors using hybrid DFPT/finite displacement approach.

Raman calculation is fairly expensive \Rightarrow and is not activated by default (though group theory prediction of active modes is still performed)

Parameter `calculate_raman = true` in a `task=phonon` calculation.

Spectral modelling of IR spectrum is relatively simple function of activity.

$$\frac{d\sigma}{d\Omega} = \frac{(2\pi\nu)^4}{c^4} |\mathbf{e}_S \cdot \mathbf{I} \cdot \mathbf{e}_L|^2 \frac{h(n_m + 1)}{4\pi\omega_m}$$

with the thermal population factor

$$n_m = \left[\exp\left(\frac{\hbar\omega_m}{k_B T}\right) - 1 \right]^{-1}$$

which is implemented in `dos.pl` using the `-raman` flag.
